Impact assessment of NVCA PGMN groundwater levels to anticipated long-term climatic variation sensitivity

**Stephanie McPhie and Ryan Post
Nottawasaga Valley Conservation Authority
May 14, 2014**

1.0 Introduction

Climate is inherently variable. According to the Intergovernmental Panel on Climate Change (IPCC), a region's vulnerability to climate change depends on its adaptive capacity, sensitivity, and exposure to changing climatic patterns (Deressa et al., 2008). In addition, an impact assessment can be completed based on current conditions, examining exposure plus sensitivity. It is assumed that areas that are currently exposed and sensitive under current conditions will likely be more impacted under climate change, as defined through an impact assessment which could be prioritized for climate change adaptation.

To date, quantitative climate change analysis completed at the subwatershed scale in the NVCA has been limited to an agricultural-water quantity climate change sensitivity assessment utilizing the following indicators: 1) low water occurrence, 2) irrigated area, 3) surface water stress assessment, and 4) animal water use (Post, 2014). It is noted that the subwatersheds with the largest amount of agricultural activity scored the highest sensitivity to climate change (e.g. Nottawasaga River and Innisfil Creek). Alternatively, the subwatersheds that lack extensive and intensive agriculture scored the lowest sensitivity to climate change – the Mad River, Blue Mountains, and Willow Creek subwatersheds.

The program objective of the Provincial Groundwater Monitoring Network (PGMN) is to monitor water quality and groundwater levels in key Ontario aquifers in order to identify and understand long-term trends in groundwater conditions. With respect to the anticipated long term climate change, groundwater levels in both unconfined and confined aquifer settings are collectively susceptible. There is presently limited understanding how climate change will impact groundwater. The uncertainty over future precipitation distribution, e.g. seasonal distribution, prevents having any certainty with respect to evaluating groundwater impacts due to climate change. Studies in Ontario show groundwater levels increasing in some areas and decreasing in others. The NVCA maintains 16 PGMN wells at 10 locations throughout the 3,300km² watershed. Commencing in 2003, the wells are completed in three of the four regional aquifers. To date, no impact assessment completed on this time series data regarding groundwater levels related to climate change.

Advancing the NVCA's understanding of groundwater exposure to climate variability and longer-term change with the focus on water quantity, the objective of this exercise is to determine which subwatershed and aquifers in the NVCA are quantitatively more prone to low groundwater conditions using existing conditions and compare this to the climate change sensitivity ranking from Post (2014).

1.1 NVCA low water declaration summary

Through the Ontario Low Water Response (OLWR) framework, three levels of low water conditions are used to indicate the severity of the watershed conditions; based on the stream flow and precipitation indicators (Ministry of Natural Resources, 2001). The number of Level I and II declarations made by the NVCA Low Water Response Team were summarized on a sub watershed level for the period of 2003-2012, based on internal documentation e.g. media releases). This agricultural-water quantity climate change sensitivity assessment indicator used the following rationale and ranking:

- Low – Score of 1 = Did not declare a level 1 in every dry year

- Medium – Score of 2 = Did not declare a level 1 in every dry year and declared a level 2
- High – Score of 3 = Declared a level 1 in every dry year and declared a level 2

It should be noted that low water declarations (Level I or above) were made somewhere within the NVCA watershed in only six years (Table 1). Further, not every quaternary watershed declared a Level I in each of the six years, and only five quaternary watersheds declared a Level II. A Level III has not been successfully declared in the NVCA. It is noted that the Innisfil Creek and the Boyne River subwatersheds had the highest susceptibility to low water conditions.

Table 1: NVCA Water Response Team low water declaration summary for level 1 ("1") and level 2 ("2"), 2003-2012.

	2003		2004		2005		2006		2007		2008		2009		2010		2011		2012		ranking

1.2 NVCA Provincial Groundwater Monitoring Network Overview

The NVCA operates 16 PGMN monitoring wells at 10 sites within the watershed (Table 2; Figure 1). The majority of the wells are concentrated in the central-eastern aspect of the watershed with one well (W486-2) located west of the Niagara Escarpment.

Physiographically, the wells are overwhelmingly concentrated in the Simcoe Uplands and Simcoe Lowland units. All wells are completed in unconsolidated overburden sediment.

Hydrostratigraphically, the wells are screened into three of the four main regional aquifers: no well is completed into the deep regional aquifer 4. Three wells are completed into unconfined aquifer conditions (W281-1, W291-1, and W292-1) and the remainder in confined settings.

Although data collection commenced in 2002 for some wells, the NVCA has varying amounts of GW level data for the 16 PGMN wells since program inception. The limited amount of useable years is reflective of operational issues and the fact that three NVCA PGMN wells are less than five years old (i.e. W479-1, W490-1, and W486-2).

Table 2 - NVCA PGMN well summary.

Well	Subwatershed	Physiographic region	Hydro-Stratigraphic Unit	Confined/Unconfined	Corrected Time Series		Percent Complete
					Start	Finished	
W223-1	LSRCA	Simcoe Uplands	A3	confined	2-Sep-03	8-May-13	82.67
W224-1	Innisfil	Oak Ridges Moraine	A3	confined	12-Dec-02	4-Nov-13	59.71
W230-1	Pine River	Simcoe Lowlands	A3	confined	25-Mar-03	4-Nov-13	79.36
W231-1	Middle Nott.	Simcoe Lowlands	A3	confined	6-Feb-03	5-Nov-13	63.16
W232-2	Lower Nott.	Simcoe Lowlands	A3	confined	2-Jun-03	4-Nov-13	79.39

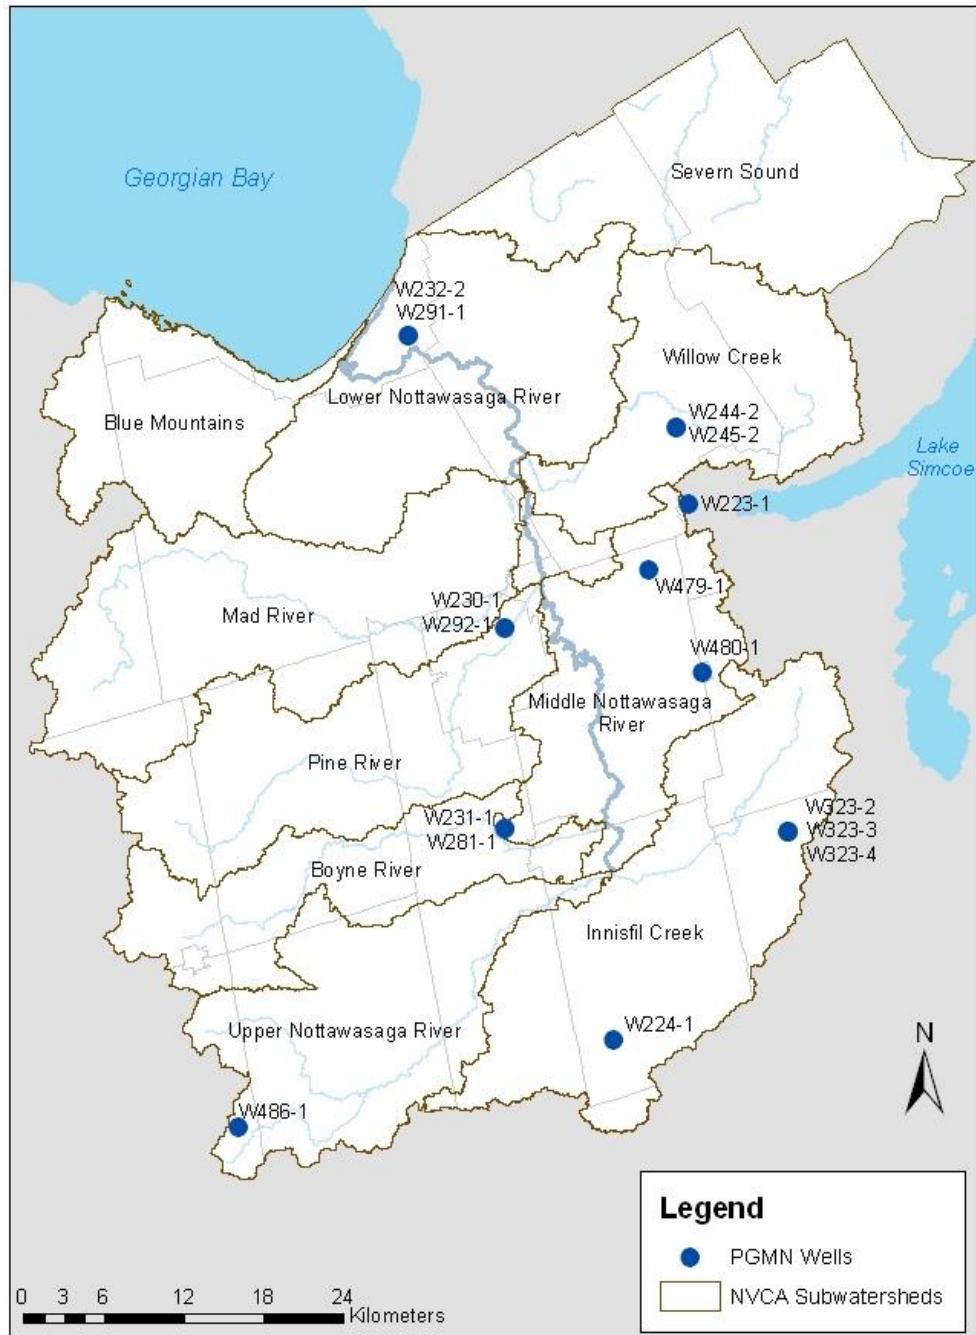

Figure 1 – NVCA subwatershed and NVCA PGMN wells

2.0 Methodology

This exposure analysis occurred in the NVCA subwatersheds where a PGMN well is present and corresponds to: Innisfil Creek, Pine River, Willow Creek, Lower Nottawasaga River, Middle Nottawasaga River, and the Upper Nottawasaga River subwatersheds. Absent subwatersheds include Blue Mountains, Mad River, and Boyne River.

This exercise used the NVCA PGMN data set for the period of 2003-2012.

A complete record is defined as >75% of the annual record, or >6570 hourly reading. It is noted where wells lack the complete annual data set, NA was used.

From McPhie and Post (2014), the following methodology was applied to determine the exposure of groundwater levels to low water conditions. The number of days a well numerically occurred in Level I/II/III on an annual basis from 2003 to 2012 was summed up annually. The scoring consisted of a day at Level I= 1, a day at Level II = 2, and a day at Level III =3. The Level I/II/III were determined via percentiles: Level I equals the 25th percentile, Level II equals the 10th percentile, and Level III equals the 5th percentile. From each well dataset, the respective levels were determined using the 30-day moving average pivot table. Lastly, a declaration table was developed stating the dates when a Level I, II or III occurred. To simplify the data, a low water level was not declared if it occurred for a period of time of 5 consecutive days or less.

To determine the exposure ranking, the data was normalized from 0 to 10 by using the following formula:

$$= x \left(\frac{10}{MAX} \right)$$

X= total score per well

Max = maximum value of the Nottawasaga Watershed (max=700)

The scale 0-10 was subdivided into:

Score 1: Low 0-3, low exposure to low water conditions

Score 2: Medium 4-7, moderate exposure to low water conditions

Score 3: High 8-10, high exposure to low water conditions.

The wells were grouped in order to calculate the scores per subwatershed and aquifer. The scores were added and the same methodology was used to scale the data from 0-10 and to determine the score per subwatershed and aquifer.

3.0 Results

Table 3 scores the individual well exposure ranking on a per year basis. NA indicates that <75% of the data record was available. PGMN well W223-1 was not included since it is not located within the NVCA watershed. The summary of ranking per year per subwatershed is outlined in Table 4. Lastly, an exposure analysis was completed on the individual aquifer system as outlined in Table 5. In addition, Appendix A provides a summary of the low water declaration duration periods for each well and Appendix B outlines the number of days that the Level I/II/III were declared for the 2003-2012 duration. Lastly, Appendix C summarizes the record of completeness per well.

Table 3 - Exposure ranking per well per year.

Year	Innisfil Creek				Pine River		Willow Creek		Lower Nottawasaga		Middle Nottawasaga River				Upp Nott .

2009	1	1	1
2010	2	1	1
2011	1	1	1
2012	1	1	1

4.0 Discussion and conclusions

When the data is normalized and summed, Innisfil Creek and Willow Creek are the most susceptible subwatershedsto low water conditions regarding groundwater level where data is available. Excluding the Upper Nottawasaga River subwatershed where the data is limiting, the least impacted subwatershed is the Pine River. Also, the completed impact assessment per aquifer indicates that the regional aquifer A2 (n=2 PGMN wells) is the least susceptible whereas regional aquifer A3 (n=8 PGMN wells) is the most impacted to climate change. It is noted that the A1 aquifer unit contains both PGMN wells completed into unconfined and confined aquifer environments (n=6 PGMN wells). No PGMN wells are completed into the regional aquifer A4. Therefore, the regional aquifer A3 in the Innisfil Creek and the Willow Creek subwatersheds are considered to be the most prone to impact climate change based on the limited PGMN datasets.

The results generated from this study on a subwatershed scale align consistently with the low water declaration level indicator used in the agricultural-water quantity climate change sensitivity assessment completed by Post (2013; Table 6). The exception is the Pine River subwatershed which may be attributed to the other indicators used by Post (2014). It is noted that three other indicators were analyzed for the agriculture sensitivity assessment including surface water stress assessment, irrigated area, and animal water demand. The sensitivity assessment concluded that the watersheds with the largest amount of agricultural activity scored the highest (e.g. Nottawasaga River and Innisfil Creek). This area includes extensive irrigated potato and sod crop lands and noted historical low water conditions. It is also noted that the Nottawasaga River subwatershed is roughly three times the size of any of the other quaternary watersheds and, as a result, the number of animals in this area may be reflective of the area and not necessarily the density of animals.

In short, that the Innisfil Creek has the highest current impact related to the high agricultural sensitivity (Post, 2014) and the results generated from this report to climate change.

Table 6—comparison of the groundwater level exposure ranking (this study) against the low water declaration level climate change sensitivity analysis (Post 2104).

Subwatershed	Groundwater level exposure ranking	Low Water Declaration Level – Climate change sensitivity ranking
Innisfil Creek	3	3
Pine River	1	2
Willow Creek	2	1
Lower Nott. River	2	2
Middle Nott. River	2	2
Upper Nott. River	1	2

It is noted that this project is limited to the PGMN data set. Therefore, while this desktop analysis is deemed not to be extremely comprehensive, it provides a satisfactory start and could be used as a framework for future groundwater exposure analysis studies in support of climate change work.

From this study, the following recommendations are noted:

- Building on this report, an impact assessment should be also completed using modelled surface water low water levels as defined from the Ontario Low Water Response Protocol.
- Additional groundwater low water exposure analysis should be completed in other (sub) watersheds where the historical groundwater low water declaration periods are known and defined using the 25th, 10th, and 5th percentiles.
- Consideration should be given to develop a detailed provincial climate change impact assessment.
- Consideration should be warranted to undertake a comprehensive groundwater sensitivity assessment at the subwatershed or suitable scale that involve indicators such as but not limited to baseflow index, percentage of shallow water wells, availability of deeper aquifers, percentage of wetland cover, areas where groundwater quality is poor, etc.
